Tackling the challenge of knowledge management and discovery at a massive scale

- Database modelling and integration has long been a focus of Information Technology research and development. Classic example being the application of RDBMs for commercial apps.
- A major and accelerating trend is the focus of data integration from business and enterprise applications to scientific and personal applications.
- Exponential growth of data with the spread of the Internet, Web and the multitudes of automatic data generation and collection devices.

This trend is expected to continue in the foreseeable future.

## Importance of Problem

- Current computational methods cannot handle magnitude and dimensionality of the data
- Decision makers and Scientists need techniques to help form hypotheses and make evidence based decisions

Tools are required to integrate, distill, and make sense of data.

## Extracting

- implicit,
- *previously unknown*,
- potentially useful

## information from data

- Needed: programs that detect patterns and regularities in the data
- Strong patterns → good predictions
  - Problem 1: most patterns are not interesting
  - Problem 2: patterns may be inexact (or spurious)
  - Problem 3: data may be garbled or missing

## Algorithms for acquiring structural descriptions from examples

- Structural descriptions represent patterns explicitly
- Can be used to predict outcome in new situation
- Can be used to understand and *explain* how prediction is derived (may be even more important)

Methods originate from artificial intelligence, statistics, and research on databases

## Dictionary definitions of “learning”:

- To get knowledge of by study, experience, or being taught
- To become aware by information or from observation
- To commit to memory
- To be informed of, ascertain; to receive instruction

→ Difficult to measure; Trivial for computers

## Operational definition:

- Things learn when they change their behaviour in a way that makes them perform better in the future.
- Does learning imply intention?

### ML concepts core definitions attributes

### Resources Books Tools

## Supervised learning

- *Teach* the computer how to do something (*by example*), then let it use its new-found knowledge to do it
- Labeled data: for given inputs, provide the expected output (“the answer”)
- Infer a function mapping from inputs to outputs

## Unsupervised learning

- Let the computer *learn how to do something*
- Determine structure and patterns in data
- Unlabeled data: Don’t give the computer “the answer”

The distinctions between Data Mining and Machine Learning are not cut-and-dried.

Data mining is primarily about discovering something hidden in your data, that you did not know before, as “new” as possible.

*Knowledge obtained from data.*

Machine learning emphasises algorithms used to generalise existing knowledge to new data, as accurately as possible.

*Techniques used to learn from data.*

Data mining applications typically use a lot of machine learning techniques. For example a pattern in a data set that is useful for generalisation might represent new knowledge.

- The input to a machine learning system consists of:
  - *Instances*: the individual, independent examples of a concept  
*also known as exemplars*
  - *Attributes*: measuring aspects of an instance  
*also known as features*
  - *Concepts*: things that we aim to learn

# Example: Supervised Learning (Classification)

**attributes**

### Resources

Books  
Tools

- Values are distinct symbols (e.g. {sunny,overcast,rainy})
  - values themselves serve only as labels or names
- Also called *categorical*, *enumerated*, or *discrete* (NB. “enumerated” and “discrete” imply an order which tends not to exist)
- Special case: dichotomy (“boolean” attribute)
- No relation is implied among nominal values (no ordering or distance measure), and only equality tests can be performed

### ML concepts

core definitions  
**attributes**

### Resources

Books  
Tools

- An explicit order is imposed on the values (e.g. {hot,mild,cool} where  $\text{hot} > \text{mild} > \text{cool}$ )
- No distance between values defined; addition and subtraction don't make sense
- Example rule:  $\text{temperature} < \text{hot} \rightarrow \text{play} = \text{yes}$
- Distinction between nominal and ordinal not always clear (e.g. outlook)
